Background and Methodology

Traumatic brain injuries can affect health-related quality of life. Still, little research exists to assess predictors of TBI-related health and quality of life in low- and middle-income countries (LMICs) in Eastern Europe

The aim of the research was to assess the broad symptoms among TBI patients from Armenia, Georgia, Republic of Moldova using the EQ-5D-5L, a tool measuring self-reported health-related quality of life

Data was collected between March and September 2019 using TBI registries and patients completed the EQ-5D-5L scale at discharge to document self-reported health outcomes

Results

- 31% of the entire cases collected with the TBI registry completed the EQ-5D-5L form (350 patients)
- Most of them were adults between 45-69 years (37%), followed by 25-44 years (25%) and children between 8 -15 years (22%)
- Males (60%), unintentional injuries (90%), falls (50%), followed RTI (26%)
- Mild TBIs (80%), mobility (20%), self-care (24%), usual activities (32%), pain/discomfort (50%), and anxiety/depression (34%)
- EQ-VAS (0 -100): mean = 80.40, median = 90 (SD = 20.69)
- A multiple linear regression model showed that GCS score, loss of consciousness, post-traumatic amnesia, and consciousness alteration predicted self-reported overall health ($F(6,322) = 21.004, p<.001$), with an R^2 of .281
